Stata

tabulate2 - Two-way tables

Main by/if/in Weights Advanced

Row variable: Gender

Column variable: Alcohol

Test statistics

- ☐ Pearson's chi-squared
- ☐ Fisher's exact test
- ☐ Goodman and Kruskal's gamma
- ☐ Likelihood-ratio chi-squared
- ☐ Kendall's tau-b
- ☐ Cramer's V

Cell contents

- ☐ Pearson's chi-squared
- ☐ Within-column relative frequencies
- ☐ Within-row relative frequencies
- ☐ Likelihood-ratio chi-squared
- ☐ Relative frequencies
- ☐ Expected frequencies
- ☐ Suppress frequencies

☐ Treat missing values like other values

☐ Do not wrap wide tables

☐ Show cell contents key

☐ Suppress value labels

☐ Suppress enumeration log

Strengths of Stata

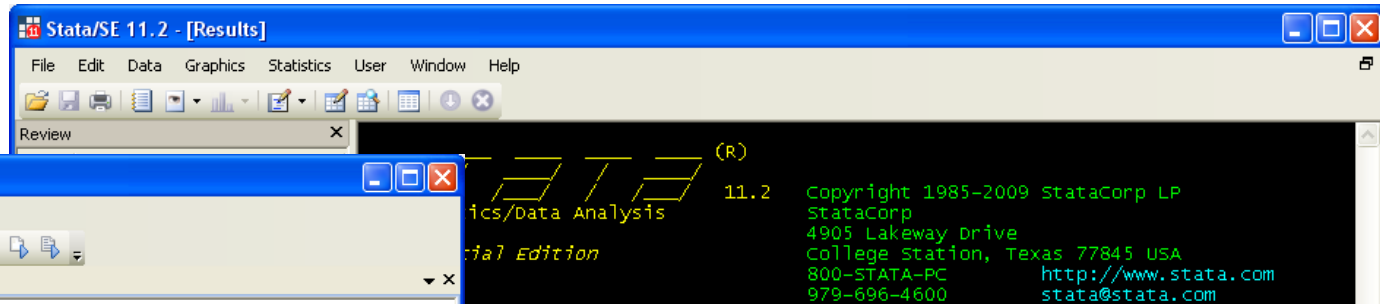

- Users can write and share new functions that extend Stata's capability
- Good customer support
- High-quality, flexible graphics
- Easy to get started and learn
- Easy to program
- Cheaper than SPSS or SAS!

Some Stata technicalities

- Four “flavors”: Small Stata, IC, SE, MP
- Increasing memory capacity
- Serious research requires SE
- MP is for multi-core processors (CPU)
- Own .dta data file format – but can import

Ways to carry out analyses

- Drop-down menu, select options
- Type command and press <return>
- Keep commands in a do-file, highlight them and click <Do> or press <Control-D> / <Shift-
Cmd-D

- Do-files are the best approach

Advantages of using do-files

- Instant audit trail
- Facilitates collaboration
- Helps you remember what you did
- Saves you a lot of time
- Some journals will publish as web supplement
- Reproducible research

Good practice with do-files

- Have one file for the project if possible
- Include all data cleaning and editing
- Add lots of annotations to help you remember and others to understand what you did
- Use **clear** and **replace** options and **capture** to avoid error messages
- Any information that is used repeatedly can be stored in memory once using **local** or **global**

Log files

- log using “mylog.smcl”, smcl replace
- Records everything that happens into a file in Stata’s own SMCL format, until you type:
- log close
- You can also use plain text format
- Logging is a very good idea, even if you only look at it when things go wrong.

Opening data files

- The File-Open menu works like any other software, and looks for Stata .dta files
- You can type **use “mydata.dta”** to open from the command line
- You can import from a variety of other formats
- **import excel** and **import delimited** are import commands for other file formats
- We will use built-in example data with the **sysuse** command

Summarizing data

- These are commands you will use a lot:
- **summarize bp_before**
- **tabulate agegrp**
- **tabulate sex agegrp, row**
- **tabstat bp_after, by(agegrp) stat(n mean sd)**

Finding help

- The single most important skill!
- Even experienced users look stuff up
 - `help tabstat`
 - `h tabstat`
 - `hsearch table statistics`
- Statalist e-mail group and archives
- The Stata Journal
- Stata Press books
- Google “... in Stata”

Processing data

- We will cover this in a lot more detail in the next two lectures
- Some ways to make and change data
- **generate change = bp_before – bp_after**
- **edit ...** then click and type
- **recode bp_after (0/139 = 1) (140/999 = 2),
generate(bp_group)**

Labelling data

- **label var change “Change in blood pressure”**
- **label define bplab 1 “Final BP < 140” 2 “Final BP 140+”**
- **label values bp_group bplab**
- Your labels are added into tables and graphs

Entering data directly

- **clear all**
- **set obs 100** makes 100 blank rows
- **generate x=.** Makes a variable called x which is empty
- **edit**
- And off you go...

Miscellaneous

- **set more off, permanently** gets rid of the annoying –more– link that you have to click on to see your output.
- Preferences menu to change color scheme
- **cd** changes the directory Stata is working in
- You can abbreviate a lot of commands (e.g. **tab sex bp_group**)
- And variable names too, if unambiguous

Selecting part of the data

- **ttest bp_after=bp_before** is a t-test on all data
- **ttest bp_after=bp_before if patient<101** does the same thing, but only on patients with ID numbers up to 100
- **ttest bp_after=bp_before in 21/40** does a t-test on rows 21 to 40 in the file
- **bysort sex: ttest bp_after=bp_before** will run the t-test once for men and once for women

More tricks

- **quietly:** will suppress output from any command that follows
- Most commands save extra stats that you can retrieve with names like **r(mean)** or **e(b)** – they are listed at the end of help files
- Commands that are very long can **///**
- be split over lines using three slashes like this
- Stata uses scientific notation: -4.72e-09 means -0.00000000472
